Description

BACKGROUND OF THE INVENTION5 Field of the Invention

Hybrid DNA technology permits the transcription and translation of genes to produce desired polypeptide products. For the most part, the polypeptide products that are of interest are associated with mammalian genes, while the choice of host cells has been primarily directed to prokaryotes and lower eukaryotes, e.g. fungi, especially yeast due to ease of propagation and genetic manipulation. In developing a methodology for producing DNA constructs which provide efficient production of a desired polypeptide, one must develop a protocol which allows for the insertion and excision of DNA fragments in an ordered way. Frequently, the various regulatory signals, replication system, markers and the structural gene(s) of interest will come from diverse sources. Therefore, one must develop a strategy which allows for endonuclease cleavages, insertions and excisions in an appropriate sequence, which provides for the DNA fragments being aligned in the correct orientation and the proper spatial relationship. Furthermore, the presence of sequences which do or could interfere with the efficient transcription, translation or propagation of the desired structural gene, must be avoided or may be present only where they do not have a detrimental effect.

In addition to the strategy involved with the preparation of the DNA construct, there is also the considerations of the choice of sequences which encode for the regulatory signals and expression products, their individual interactions, their effect on the host, the efficiency with which the energy of the host is diverted to the production of the desired polypeptide, and the ease of isolation of the polypeptide product. Therefore, each development of a process for the production of a particular polypeptide becomes an intellectual exercise in experimental design, procedural organization, and investigation.

Description of the Prior Art

The human DNA sequence for human insulin may be found in Bell et al., Nature (1979) 282:525-527. Production of rat "pre"-proinsulin polypeptide fragments in bacteria is described in U.S. Patent No. 4,338,397. Kurjan and Herskowitz, Cell (1982) 30:933-943 describe a putative α -factor precursor containing four tandem copies of mature α -factor, describing the sequence and postulating a processing mechanism. Kurjan and Herskowitz, Abstracts of Papers presented at the 1981 Cold Spring Harbor Meeting on The Molecular Biology of Yeast, p. 242, in an Abstract entitled, "A Putative Alpha-Factor Precursor Containing Four Tandem Repeats of Mature Alpha-Factor," describe the sequence encoding for the α -factor and spacers between two of such sequences. U.S. Patent No. 4,338,397, col. 3 and 4, provides for useful definitions, which definitions are incorporated herein by reference.

SUMMARY OF THE INVENTION

Method and compositions are provided for the production of a "pre"-proinsulin in a yeast host and secretion of processed "pre"-proinsulin into the nutrient medium. The DNA constructs are produced by joining of DNA sequences from diverse sources, providing a construct which is stably replicated in a yeast host and results in efficient high level production of processed "pre"-proinsulin into the nutrient medium, where it may be isolated in high yield.

DESCRIPTION OF SPECIFIC EMBODIMENTS

Novel DNA constructs are provided for the efficient production of mammalian "pre"-proinsulin in a yeast host and processing of the "pre"-proinsulin. The constructs provide for transcription and translation of mammalian "pre"-proinsulin and processing and secretion of the polypeptide product into the nutrient medium. The construction therefore involves a DNA construct which includes a replication system capable of stable maintenance in a yeast host; an efficient promoter; a structural gene including leader and processing signals joined to the coding region for proinsulin in reading frame with the secretion leader and processing coding sequence, and a terminator sequence downstream from the structural gene. Optionally, other sequences can be provided for transcriptional regulation, amplification of the gene, exogenous regulation of transcription, and the like.

The "pre"-proinsulin intends a gene encoding for human proinsulin in reading frame with a leader

sequence and processing signals efficiently recognized by the yeast host. Thus, "pre" intends the secretion and processing signals associated with the yeast host as distinguished from the human sequences naturally present with proinsulin for processing the native prepropeptide to proinsulin.

In preparing the construct, it is necessary to bring the individual sequences together in a predetermined order to ensure that at each stage, sequences which are present are not disturbed, so as to detrimentally affect their function, and that each of the sequences which are introduced are properly positioned in relation to the other sequences, so as to be able to fulfill their individual functions. Furthermore, adaptor molecules may be employed to advantage for organizing the construct.

The proinsulin gene which is employed may be chromosomal DNA, cDNA, synthetic, or combinations thereof. Since the proinsulin gene is a mammalian gene and the regulatory, leader and processing, and transcriptional terminator signals will be sequences derived from and recognized by the host, it will be useful to join the several sequences by means of connecting or adaptor sequences. Thus, by appropriate choice of restriction sites, one can provide the proinsulin gene restricted internally and proximal to the 5'-terminus of the coding strand, so as to lack a number of base pairs. Similarly, the leader and processing signal sequences may be restricted internal and proximal to the 3'-terminus of the coding strand, so as to lack a plurality of base pairs. (Unless otherwise indicated, the 5'- and 3'- designations intend the coding strand.) The restriction sites are chosen so that the adaptor results in the proper reading frame for the proinsulin gene.

Since the adaptor can be prepared synthetically, it is desirable that the codons of the adaptor be those preferentially utilized by the yeast host, e.g. as occur in glycolytic enzymes, rather than employing the naturally occurring mammalian codons. The adaptor will have from about 20 to 40, more usually from about 25 to 35 bases in the coding sequence and may have cohesive ends or butt ends, preferably cohesive ends. Desirably, the termini of the adaptor will have different cohesive ends, so as to ensure the proper orientation of the adaptor. Therefore, the two ends to be linked will also have different termini.

For the leader and processing signals, one may use a naturally occurring DNA sequence from yeast. Polypeptides which are secreted by yeast include α -factor, a-factor, and the like.

The subject invention will be illustrated with the cDNA gene for proinsulin used with the regulatory, leader and processing signals, and transcriptional terminator of yeast α -factor.

The yeast α -factor may be restricted with HindIII and SalI. HindIII cleaves in the processing signal of the α -factor, cleaving at the second base in the coding strand of the glu codon, while the recognition sequence completes the glu codon and encodes for ala. The SalI site is prior to the α -factor transcriptional terminator.

The human proinsulin cDNA is restricted with EcoRI to provide a fragment (EcoRI-EcoRI) having a complete coding sequence for proinsulin, as well as flanking sequences. By partially digesting the EcoRI-EcoRI fragment with EcoRII, cleaving internal to the coding sequence, a truncated fragment is obtained lacking a portion of the coding sequence at the 5'-terminus. The last base pairs may be provided by an adaptor, which will join the leader and processing signal fragment (HindIII site) with the EcoRII-EcoRI fragment in proper reading frame. The adaptor may be produced as a single fragment or may be produced by joining two or more single strands together. The adaptor recreates the necessary codons of the processing signal and gene to be expressed.

At the other end of the fragment containing the cDNA gene for proinsulin is the EcoRI recognition sequence. The α -factor gene has a SalI restriction site at base 533 from the first base of the f-met codon. A small EcoRI-SalI adaptor serves to join the two ends in this 3'-non-coding region and thus serves to restore the α -factor transcriptional terminator to the construct.

Conveniently, the promoter which is employed may be the promoter associated with the leader sequence. In this manner, one can provide a 5'-portable element which contains both the promoter and the leader sequence in proper spatial relationship for efficient transcription. One may further include a transcriptional terminator to create a "cassette" consisting of: promoter/leader - heterologous gene - terminator. This is achieved by isolating a DNA fragment which includes an intact gene from a yeast host and the upstream and downstream transcriptional regulatory sequences of the gene, where the gene expresses a polypeptide which is secreted by a yeast host. This has been exemplified above with α -factor.

The proinsulin cDNA will have its own stop codons to ensure that the C-terminus of the polypeptide is the same as the naturally occurring C-terminus.

Alternatively, one may replace the naturally occurring promoter by other promoters which allow for transcriptional regulation. This will require sequencing and/or restriction mapping of the region upstream from the leader sequence to provide for introduction of a different promoter. In some instances, it may be desirable to retain the naturally occurring promoter and provide a second promoter in tandem, either upstream or downstream from the naturally occurring promoter.

A wide variety of promoters are available or can be obtained from yeast genes. Promoters of particular

interest include those promoters involved with enzymes in the glycolytic pathway, such as promoters for alcohol dehydrogenase, glyceraldehyde-3-phosphate dehydrogenase, pyruvate kinase, triose phosphate isomerase, phosphoglucose isomerase, phosphofructokinase, etc. By employing these promoters with regulatory sequences, such as operators, repressors and derepressors, and using a host having an intact regulatory system, one can regulate the expression of the processed "pre"-proinsulin. Thus, various small organic molecules, e.g. glucose, may be employed for the regulation of production of the desired polypeptide

One may also employ temperature-sensitive regulatory mutants which allow for modulation of transcription by varying the temperature. Thus, by growing the cells at the non-permissive temperature, one can grow the cells to high density, before changing the temperature in order to provide for expression of the processed "pre"-proinsulin.

Other capabilities may also be introduced into the construct. For example, some genes provide for amplification, where upon stress to the host, not only is the gene which responds to the stress amplified, but also flanking regions. By placing such a gene upstream from the promoter and the other regulatory signals providing transcriptional control of the "pre"-proinsulin, and stressing the yeast host, plasmids may be obtained which have a plurality of repeating sequences, which sequences include the "pre"-proinsulin gene with its regulatory sequences. Illustrative genes include metallothioneins and dihydrofolate reductase.

The construct may include in addition to the leader sequence fragment, other DNA homologous to the host genome. If it is desired that there be integration of the proinsulin gene into the chromosome(s), integration can be enhanced by providing for sequences flanking the proinsulin gene construct which are homologous to host chromosomal DNA.

The replication system which is employed will be recognized by the yeast host. Therefore, it is desirable that the replication system be native to the yeast host. A number of yeast vectors are reported by Botstein et al., *Gene* (1979) 8:17-24. Of particular interest are the YEp plasmids, which contain the 2 μ m plasmid replication system. These plasmids are stably maintained at multiple copy number. Alternatively or in addition, one may use a combination of ARS1 and CEN4, to provide for stable maintenance.

After each manipulation, as appropriate, the construct may be cloned so that the desired construct is obtained pure and in sufficient amount for further manipulation. Desirably, a shuttle vector (i.e., containing both a yeast and bacterial origin of replication) may be employed so that cloning can be performed in prokaryotes, particularly *E. coli*.

The plasmids may be introduced into the yeast host by any convenient means, employing yeast host cells or spheroplasts and using calcium precipitated DNA for transformation or other conventional techniques. The modified hosts may be selected in accordance with the genetic markers which are usually provided in a vector used to construct the expression plasmid. An auxotrophic host may be employed, where the plasmid has a gene which complements the host and provides prototrophy. Alternatively, resistance to an appropriate biocide, e.g. antibiotic, heavy metal, toxin, or the like, may be included as a marker in the plasmid. Selection may then be achieved by employing a nutrient medium which stresses the parent cells, so as to select for the cells containing the plasmid. The plasmid containing cells may then be grown in an appropriate nutrient medium, and the desired secreted polypeptide isolated in accordance with conventional techniques. The polypeptide may be purified by chromatography, extraction, etc. Since the polypeptide will be present in mature form in the nutrient medium, one can cycle the nutrient medium, continuously removing the desired polypeptide.

The following examples are offered by way of illustration and not by way of limitation.

EXPERIMENTAL

1. EcoRI digestion of phins 1-19

(~700 μ g) phins 1-19 (517bp cDNA containing the entire human proinsulin gene, cloned in the EcoRI site of pBR328) was incubated with ~1600 units of EcoRI (New England Biolabs) in one ml at 37 $^{\circ}$ C for approximately 4.5h (until completion) under the buffer conditions prescribed by the manufacturer. (phins 1-19 is derived from the plasmid described by Bell et al., *supra*, by PstI cleavage, Bal31 resection, attachment of EcoRI linkers and insertion into pBR328.)

Isolation of EcoRI-EcoRI fragment of phins 1-19 containing human proinsulin gene

The EcoRI-EcoRI fragment was isolated by 5% non-denaturing polyacrylamide gel electrophoresis. The gel was stained in a solution of 1 μ g/ml ethidium bromide for approximately 10min, and visualized under

long wavelength UV light. The band corresponding to the 517bp fragment was cut out and isolated from the gel by electroelution (Smith, Methods in Enz. (1980) 65:371-380). The DNA was concentrated and purified by passing it through an Elutip-d column[®] (Schleicher and Schuell Inc.) under the prescribed conditions.

5 2. Partial digestion of EcoRI-EcoRI piece with EcoRII

The EcoRI-EcoRI fragment (~17μg) was incubated with ~3 units of EcoRII (Bethesda Research Labs) in a volume of 170μl at 37° C under the prescribed buffer conditions. Aliquots of equal volume were removed at 18, 21 and 25min.

10 Isolation of the EcoRII-EcoRI piece (long fragment)

The 392bp EcoRII-EcoRI fragment was isolated by polyacrylamide gel electrophoresis, followed by electroelution and Elutip-d chromatography as described above.

15 3. Ligation of EcoRII-EcoRI fragment to synthetic fragments

The EcoRII to EcoRI partial digest fragment containing most of the insulin coding region was evaporated to dryness from water (80μg, 0.35 picomoles) in a siliconized 1.5ml Eppendorf tube. To the pellet, 10²⁰ picomoles of the 5'-phosphorylated synthetic fragments 3 and 4 and 25 picomoles of 2 and 5 were added to bring the volume to 14μl. Fragments 2-5 had the following DNA sequences (indicated 5'→3'):

2. ACAAAGCTTC
3. TTGTGAACCAACACCTGTGCGGCTCACA
- 25 4. CCAGGTGTGAGCCGCACAGGTGTTGGTTC
5. AATTGATAAG

To this was added 5μg of poly-A (5μl), 250mM EDTA (1μl), 2M sodium acetate (20μl). The solution was heated to 60° C for 5min to inactivate residual kinase and then 25 picomoles of the 5'-hydroxy synthetic fragments 1 and 6 were added. Fragments 1 and 6 had the following DNA sequences:

- 30 1. AGCTGAAGCTT
6. TCGACTTATCA

This protocol thus prevents concatemer formation. These fragments bridge the codons from the yeast α-factor processing signals to the EcoRII restriction site in proinsulin at the codons for his and leu and also provide the adaptor bridging the EcoRI restriction site of the proinsulin gene-containing fragment and the 35 Sall restriction site of the fragment containing the yeast α-factor, where both the EcoRI and Sall sites are downstream from their respective coding regions.

The mixture was vortexed, 200μl of 95% ethanol was added and the DNA was precipitated by holding the tube at -80° C for 20min. After centrifugation for 10min at 12,800G, the solution was decanted, washed with cold ethanol and evaporated to dryness. Annealing of the fragments was achieved by adding 18μl of 40 water, vortexing, heating to 90° C and cooling to 14° C over a 1h period. The solution was adjusted to contain 50mM Tris-HCl (pH 7.8), 10mM MgCl₂, 1mg/ml spermidine, 10mM dithiothreitol, 1mM ATP (ligation buffer) in a total volume of 27μl.

Ligation was initiated by the addition of 6 Weiss units of T4 DNA ligase (3μl). After 2h at 14° C the anticipated 443bp HindIII to Sall fragment was isolated by 7% polyacrylamide gel electrophoresis under 45 non-denaturing conditions. The band was visualized by staining with ethidium bromide (0.5μg/ml), cut out, and electroeluted. The contents of the bag were removed, 5μg of poly-A was added, the DNA ethanol precipitated and dried. The fragment was 5'-phosphorylated with T4 polynucleotide kinase (3 units) at 37° C for 1h in a total of 20μl of the ligation buffer.

50 4. Ligation of the HindIII-Sall α-factor-proinsulin fusion fragment into pAB113

pAB113 is a plasmid comprising a 1.8kb EcoRI fragment containing the yeast α-factor gene cloned in the EcoRI site of pBR322 in which the HindIII and Sall sites have been deleted. pAB113 is derived from plasmid pAB101, which contains the yeast α-factor gene as a partial Sau3A fragment cloned in the BamHI 55 site of plasmid YEp24. pAB101 is obtained by screening a yeast genomic library cloned in YEp24 using a synthetic oligonucleotide probe homologous to the published α-factor coding region (Kurjan and Herskowitz, Abstracts 1981 Cold Spring Harbor Meeting on the Molecular Biology of Yeasts, p. 242). pAB113 was completely digested with endonucleases HindIII and Sall.

The sample containing the ligation product prepared above was heated to 60°C and 100ng of the digested pAB113 was added. The solution was cooled to 14°C over a 15min period, 2 Weiss units of T4 ligase were added, and the ligation was conducted for 2h at 14°C.

5 Transformation of E. coli HB101 with pAB113 containing the insert and testing transformants

After ethanol precipitation, the pellet was taken up in 75mM CaCl₂ and used to transform competent E. coli HB101 cells.

Eight transformants were obtained, from each of which plasmid DNA was extracted (Birboim and Doly, J. Nuc. Acids Res. (1979) 7:1513. The recombinant plasmids were digested with PstI and Sall and then electrophoretically examined for yield of the anticipated fragments of 319, 207, 79, 48, 31 and 27bp characteristic of the α -factor-proinsulin insert. Five of the eight transformants, indicated as pyins -1, -2, -3, -4, -5 contained the α -factor-proinsulin insert. Preparations of plasmid DNA from one liter cultures were made for each of the positive transformants.

15 5. EcoRI digestion of pyins -1, -2, -3, -4, -5

Plasmid DNA (140µg) from each of the transformants was incubated for 4h with 240 units of EcoRI (BRL) in a volume of 200µl under prescribed buffer conditions.

20 Isolation of the EcoRI-EcoRI fragment

The 2056bp EcoRI-EcoRI fragment was isolated by 5% polyacrylamide electrophoresis (alternatively, agarose could be used). The gel was stained with ethidium bromide, and the anticipated UV-visualized band was excised. The DNA was isolated by electroelution and purified by chromatography as described above.

6. Ligation of EcoRI-to-BamHI adaptor molecules onto EcoRI-EcoRI fragment

Each "pyin" clone (~4µg) was incubated with 1.0µg of the 5'-phosphorylated EcoRI-to-BamHI adaptors of the following DNA sequences in the presence of 2000 units of T4 DNA ligase (New England Biolabs). 5'-GATCCCTCTAGG-3' and 5'-AATTCCTAGAGG-3'

The reaction was conducted in a volume of 900µl of the prescribed buffer for 2.5h at 18°C. The sample was heated to 65°C for 10min, phenol extracted, and digested with 100 units of BamHI (BRL) in 250µl of the prescribed buffer at 37°C for 4h.

35 The BamHI-BamHI α -factor-proinsulin fragment was purified by 1% agarose gel electrophoresis, followed by electroelution and subsequent column chromatography as above.

7. Ligation of BamHI-BamHI fragment into the BamHI site of pC1/1

40 The BamHI-BamHI fragment of pyins-1 (0.7µg) and 0.4µg of the same fragment from the other "pyins" clones were ligated to a quantity of BamHI-digested pC1/1 corresponding to a mole ratio of 10 fragments:1 vector. (Plasmid pC1/1 is a derivative of pJDB219 (Beggs, Nature (1978) 275:104) in which the region corresponding to bacterial plasmid pMB9 in pJDB219 has been replaced by pBR322 in pC1/1. pC1/1 contains a complete 2µm replicator, yeast LEU2 gene and complete pBR322.) All the ligations were done with a DNA concentration of 5µg/ml and 800 units of T4 ligase (New England Biolabs) for 2.5h at 21°C.

45 After ethanol precipitation, the DNA was resuspended in 100µl of 75mM CaCl₂ and used to transform competent E. coli HB101 cells.

Testing of transformants for the presence of the α -factor-proinsulin insert

50 Hundreds of transformants were obtained for each "pyins" clone. Four transformants from each of the five "pyins" clones were tested by extracting the plasmid DNA and digesting it with PstI (New England Biolabs) which would yield anticipated characteristic fragments of 207, 48 and 27bp in the presence of the insert. Fourteen of the 20 transformants tested were found to contain the α -factor-proinsulin insert, each of the original "pyins" clones being represented. Plasmid preparations were made of a transformant from each of the original "pyins" clones.

The plasmids were employed to transform yeast AB103 cells (α , pep 4-3, leu 2-3, leu 2-112, ura 3-52, his 4-580) and Leu⁺ transformants selected.

Insulin radioimmunoassay of cell medium

The yeast transformants, AB103 (pYins1 or pYins5) were grown as "patches" on a minimal plate without leucine. A sterile plastic inoculating loop was used to remove some of each patch into 2ml of minimal medium without leucine. The cultures, and a control culture of AB103(pC1/1) were grown to saturation. The cells were pelleted by centrifugation for 10min at 2,500rpm in a Beckman J6B centrifuge. The supernatant was removed for RIA assay using a kit supplied by Amersham. One, 10 and 100μl of supernatant were assayed.

Expt	Clone	Conc "Insulin" (ng/ml)
1	pC1/1	0
	pYins5-2B	16
	pYins5-3A	13
	pYins5-3B	33
2	pC1/1	0
	pYins1-4A	60
	pYins5-2B	32
	pYins5-3B	22
	pYins7-1A	15
	pYins7-2A	46
	pYins8-4	48

In a lipogenesis bioassay (Moody et al., Horm. Metab. Res. (1974) 6:12-16), a 1μg sample showed 27% of the activity of insulin. The sample was obtained from the plasmid pYins1-4A as follows: For this characterization the yeast culture was centrifuged to remove cells and the supernatant medium acidified to pH 3 with acetic acid. The material was then purified by absorption to Biorex-70^R; the column was washed with 0.1N acetic acid and 50% ethanol and the material then eluted with 10mM HCl in 80% ethanol. The eluate was taken to dryness by rotary evaporation and taken up in a small volume of water. The above result demonstrates the presence of an insulin active polypeptide.

In accordance with the subject invention, novel constructs are provided which may be inserted into vectors to provide for expression of "pre"-proinsulin to provide processing and secretion. Thus, one can obtain a polypeptide having the identical sequence to the naturally occurring human insulin. By virtue of providing for secretion, greatly enhanced yields can be obtained based on cell population and subsequent preparative operations and purification are simplified.

Claims

1. A method for expressing mature insulin in yeast resulting in the processing and secretion of said mature insulin, said method comprising:
 - a) providing a yeast host transformed by a DNA construct comprising first and second DNA sequences in the same reading frame, wherein said second DNA sequence encodes a precursor sequence for mature insulin requiring processing to produce the mature insulin, and said first DNA sequence encodes a yeast leader sequence that provides for the secretion and processing of the precursor sequence from the yeast host; and
 - b) growing said transformed yeast host in a nutrient medium under conditions whereby mature insulin is secreted into the medium.
2. A method according to claim 1 wherein said yeast leader sequence comprises an alpha-factor signal peptide sequence that provides for secretion from the yeast host.

3. A method according to claim 1 wherein said second DNA sequence comprises a human insulin cDNA fragment.
4. A method for expressing mature insulin in yeast resulting in the processing and secretion of said mature insulin, said method comprising:
 - a) providing a yeast host transformed by an expression cassette comprising a heterologous gene comprising a first DNA sequence encoding a yeast alpha-factor signal peptide sequence that provides for secretion in reading frame with a second DNA sequence encoding a precursor sequence for mature insulin requiring processing to produce the mature insulin; and
 - b) growing said yeast host in a nutrient medium under conditions whereby mature insulin is secreted into said nutrient medium.
5. A method according to claim 4 wherein said second DNA sequence comprises a human insulin cDNA fragment.
6. A method according to claim 4 wherein said expression cassette is in a vector comprising a replication system recognized by said yeast host.
7. A method according to claim 4 wherein said expression cassette is in a vector comprising a replication system recognized by E. coli.
8. A method according to claim 6 wherein said replication system comprises a 2 micron plasmid sequence.
9. A DNA construct comprising first and second DNA sequences in the same reading frame, wherein said second DNA sequence encodes a precursor sequence for mature insulin requiring processing to produce the mature insulin, and said first DNA sequence encodes a yeast leader sequence that provides for the secretion of the precursor sequence from the yeast host.
10. A DNA construct according to claim 9 wherein said yeast leader sequence comprises an alpha-factor signal peptide that provides for secretion from the yeast host.
11. A DNA construct according to claim 9 further comprising a replication system recognized by yeast.
12. A DNA construct according to claim 11 wherein said replication system comprises a 2 micron plasmid sequence.
13. A DNA construct according to claim 9 further comprising a replication system recognized by E. coli.
14. A method comprising providing a host cell transformed by a DNA construct according to claim 9 and growing said host cell in a nutrient medium under conditions whereby said host cell and said DNA construct are replicated.

Revendications

1. Procédé pour l'expression de l'insuline mature dans de la levure conduisant à la maturation et à la sécrétion de ladite insuline mature, ledit procédé comprenant :
 - (a) la mise en oeuvre d'une levure hôte transformée par une construction d'ADN comprenant des première et seconde séquences d'ADN dans le même cadre de lecture, ladite seconde séquence d'ADN codant pour une séquence précurseur de l'insuline mature nécessitant une maturation pour produire l'insuline mature, et ladite première séquence d'ADN codant pour une séquence leader de levure qui assure la sécrétion et la maturation de la séquence précurseur à partir de la levure hôte; et
 - (b) la culture dans un milieu nutritif de ladite levure hôte, transformée, dans des conditions dans lesquelles de l'insuline mature est sécrétée dans le milieu.
2. Procédé selon la revendication 1, dans lequel ladite séquence leader de levure comprend une séquence de peptide signal de facteur alpha qui assure la sécrétion à partir de la levure hôte.

3. Procédé selon la revendication 1, dans lequel ladite seconde séquence d'ADN comprend un fragment d'ADNc d'insuline humaine.
4. Procédé pour l'expression de l'insuline mature dans une levure conduisant à la maturation et à la sécrétion de ladite insuline mature, ledit procédé comprenant :
 - (a) la mise en oeuvre d'une levure hôte transformée par une cassette d'expression comprenant un gène hétérologue comprenant une première séquence d'ADN codant pour une séquence de peptide signal de facteur alpha de levure qui assure la sécrétion, dans un cadre de lecture avec une seconde séquence d'ADN codant pour une séquence précurseur de l'insuline mature nécessitant une maturation pour produire l'insuline mature; et
 - (b) la culture de ladite levure dans un milieu nutritif dans des conditions dans lesquelles l'insuline mature est sécrétée dans ledit milieu nutritif.
5. Procédé selon la revendication 4, dans lequel ladite seconde séquence d'ADN comprend un fragment d'ADNc d'insuline humaine.
6. Procédé selon la revendication 4, dans lequel ladite cassette d'expression est dans un vecteur comprenant un système de réplication reconnu par ladite levure hôte.
7. Procédé selon la revendication 4, dans lequel ladite cassette d'expression est dans un vecteur comprenant un système de réplication reconnu par E. Coli.
8. Procédé selon la revendication 6, dans lequel ledit système de réplication comprend une séquence plasmidique de 2 microns.
9. Construction d'ADN comprenant des première et seconde séquences d'ADN dans le même cadre de lecture, dans lequel ladite seconde séquence d'ADN code pour une séquence précurseur de l'insuline mature nécessitant une maturation pour produire l'insuline mature, et ladite première séquence d'ADN code pour une séquence leader de levure qui assure la sécrétion de la séquence précurseur à partir de la levure hôte.
10. Construction d'ADN selon la revendication 9, dans laquelle ladite séquence leader de levure comprend un peptide signal de facteur alpha qui assure la sécrétion à partir de la levure hôte.
11. Construction d'ADN selon la revendication 9, comprenant en outre un système de réplication reconnu par la levure.
12. Construction d'ADN selon la revendication 11, dans laquelle ledit système de réplication comprend une séquence plasmidique de 2 microns.
13. Construction d'ADN selon la revendication 9, comprenant en outre un système de réplication reconnu par E. Coli.
14. Procédé comprenant la mise en oeuvre d'une cellule hôte transformée par une construction d'ADN telle que définie à la revendication 9, et la culture de ladite cellule hôte dans un milieu nutritif dans des conditions dans lesquelles ladite cellule hôte et ladite construction d'ADN sont répliquées.

Patentansprüche

1. Verfahren zum Exprimieren von reifem Insulin in Hefe unter Processing und Sekretion des reifen Insulins, mit den Schritten:
 - a) Bereitstellen eines mit einer ersten und zweiten DNA-Sequenzen in dem gleichen Leseraster enthaltenden DNA-Konstrukt transformierten Hefewirts, wobei die zweite DNA-Sequenz eine zur Herstellung des reifen Insulins ein Processing erfordernde Vorläufersequenz für reifes Insulin kodiert und die erste DNA-Sequenz eine für die Sekretion und das Processing der Vorläufersequenz von dem Hefewirt sorgende Hefe-Leader-Sequenz kodiert; und
 - b) Züchten des transformierten Hefewirts in einem Nährmedium unter Bedingungen, bei denen das reife Insulin in das Medium sekretiert wird.

2. Verfahren gemäß Anspruch 1, bei dem die Hefe-Leader-Sequenz eine für die Sekretion aus dem Hefewirt sorgende α -Faktor-Signal-Peptid-Sequenz umfaßt.
3. Verfahren gemäß Anspruch 1, bei dem die zweite DNA-Sequenz ein Human-Insulin-cDNA-Fragment
5 umfaßt.
4. Verfahren zum Exprimieren von reifem Insulin in Hefe unter Processing und Sekretion des reifen Insulins, mit den Schritten:
 - a) Bereitstellen eines Hefewirts, der mit einer Expressionskassette transformiert ist, die eine erste, eine für Sekretion sorgende Hefe- α -Faktor-Signal-Peptid-Sequenz kodierende DNA-Sequenz
10 im Leseraster mit einer zweiten, eine zur Herstellung des reifen Insulins ein Processing erfordernde Vorläufersequenz für reifes Insulin kodierende DNA-Sequenz einschließendes heterologes Gen umfaßt; und
 - b) Züchten des Hefewirts in einem Nährmedium unter Bedingungen, bei denen reifes Insulin in das
15 Nährmedium sekretiert wird.
5. Verfahren gemäß Anspruch 4, bei dem die zweite DNA-Sequenz ein Human-Insulin-cDNA-Fragment umfaßt.
- 20 6. Verfahren gemäß Anspruch 4, bei dem die Expressionskassette in einem ein von dem Hefewirt erkanntes Replikationssystem enthaltenden Vektor vorliegt.
7. Verfahren gemäß Anspruch 4, bei dem die Expressionskassette in einem ein von E. coli erkanntes Replikationssystem enthaltenden Vektor vorliegt.
- 25 8. Verfahren gemäß Anspruch 6, bei dem das Replikationssystem eine 2-Micron-Plasmid-Sequenz umfaßt.
9. DNA-Konstrukt, umfassend erste und zweite DNA-Sequenzen in dem gleichen Leseraster, wobei die zweite DNA-Sequenz eine zur Herstellung des reifen Insulins ein Processing erfordernde Vorläufersequenz für reifes Insulin kodiert und die erste DNA-Sequenz eine für die Sekretion der Vorläufersequenz aus dem Hefewirt sorgende Hefe-Leader-Sequenz kodiert.
30
10. DNA-Konstrukt gemäß Anspruch 9, in dem die Hefe-Leader-Sequenz ein für Sekretion aus dem Hefewirt sorgendes α -Faktor-Signal-Peptid umfaßt.
35
11. DNA-Konstrukt gemäß Anspruch 9, das weiterhin ein von Hefe erkanntes Replikationssystem umfaßt.
12. DNA-Konstrukt gemäß Anspruch 11, in dem das Replikationssystem eine 2-Mikron-Plasmid-Sequenz umfaßt.
40
13. DNA-Konstrukt gemäß Anspruch 9, das weiterhin ein von E. coli erkanntes Replikationssystem umfaßt.
14. Verfahren mit den Schritten des Bereitstellens einer mit einem DNA-Konstrukt gemäß Anspruch 9 transformierten Wirtszelle und Züchten der Wirtszelle in einem Nährmedium unter Bedingungen, bei
45 denen die Wirtszelle und das DNA-Konstrukt repliziert werden.
